## Heart Disease UCI

April 21, 2021

# 1 IBM Machine Learning: Classification Capstone Project

by Evangelos Tselentis - Straitouris

#### 1.1 Introduction

The heart is an amazing organ. It continuously pumps oxygen and nutrient-rich blood throughout your body to sustain life. This fist-sized powerhouse beats (expands and contracts) 100,000 times per day pumping 23,000 liters (5,000 gallons) of blood every day. To work properly, the heart (just like any other muscle) needs a good blood supply.

A heart attack (also known as myocardial infarction; MI) is defined as the sudden blockage of blood flow to a portion of the heart. Some of the heart muscle begins to die during a heart attack, and without early medical treatment, the loss of the muscle could be permanent.

Conditions such as high blood pressure, high blood cholesterol, obesity, and diabetes can raise the risk of a heart attack. Behaviors such as an unhealthy diet, low levels of physical activity, smoking, and excessive alcohol consumption can contribute to the conditions that can cause heart attacks. Some factors, such as age and family history of heart disease, cannot be modified but are associated with a higher risk of a heart attack.

#### 1.2 Dataset

For the exploration of the risk a person has to develop a heart attack (**prediction** analysis), the Heart Attack Analysis & Prediction Dataset from kaggle.com was utilized. It consists of:

- Age of the patient (age in years)
- Sex of the patient (sex; 1 = male, 0 = female)
- Exercise induced angina (exng; 1 = yes, 0 = no)
- Number of major vessels (ca; 0-3)
- Chest pain type (cp; Value 1: typical angina, Value 2: atypical angina, Value 3: non-anginal pain, Value 4: asymptomatic)
- Resting blood pressure (trestpbs; in mm/Hg on admission to the hospital)
- Cholesterol levels (chol; in mg/dl)
- Fasting blood sugar (fbs; if > 120 mg/dl, 1 = true; 0 = false)
- Resting electrocardiographic results (rest\_ecg; 0 = normal, 1 = having ST-T wave abnormality, 2 = showing probable or definite left ventricular hypertrophy by Estes' criteria)
- Maximum heart rate achieved (thalach)
- Chance of heart attack (target: Heart disease)

- A blood disorder called thalassemia (thall; 1 = normal; 2 = fixed defect; 3 = reversable defect)
- Previous peak (oldpeak; ST depression induced by exercise relative to rest 'ST' relates to positions on the ECG plot)
- Slope (slp; the slope of the peak exercise ST segment, Value 1: upsloping, Value 2: flat, Value 3: downsloping)

## 1.6 Conclusion

In this report, the heart attack dataset from UCI was explored to find the most suitable ML algorithm for the prediction of a possible myocardial infarction (classification task)

After some feature engineering of the acquired dataset, and the removal of both duplicate and outlier values, some numerical variables were explored by creating their corresponding plots.

Overall, the dataset didn't require a lot of change and is of good quality. Nonetheless, it would be beneficial if there were more than 302 observations. Further suggestions for improving the quality of this dataset are to add features that are responsible for myocardial infarctions, like the diet, smoking information of the patient, and type of diabetes (if eligible).

A correlation heatmap was then created to find which variables are correlated, to what degree, in which direction, while furthermore, it is useful for observing any multicollinearity problems.

Next, the dataset was preprocessed by creating dummy variables and scaling the numerical features before the creation of the ML models. In particular, 8 models were instantiated, a logistic regression, a k-nearest neighbors, a support vector machine, a decision tree classifier, a random forest classifier, an extra trees classifier, a gradient boosting classifier, and a bagging classifier model. Four of those (i.e. logistic regression, k-nearest neighbors, decision tree, and random forest classifier) were explored further, for tuning their hyperparameters by using grid-search.

Based on the models' accuracy findings, the most suitable algorithms are the decision tree classifier (~0.855 accuracy), the support vector machine (with approximately 0.85 accuracy score), and third, being bagging classifier model (0.84 accuracy). However, the comparison between the f1 scores shows that the best model is the extra tree classifier. Considering that all accuracy metrics and f1 scores of the best models are very similar, here the **Support Vector Machine model** was selected as the most suitable in our case.

#### 1.6.1 Next Steps

Next to our exploration would be the creation of a voting classifier model by combining the Support Vector Machine, the Extra tree classifier, and the bagging classifier model. For even better results, one could create a stacking model.

[]:
